Biodiversity Assessment and Biomass Estimation of Anjneri Hill

1. Introduction

Ecological assessment is a crucial step for land management practices. Along with assessing environmental abiotic factors such soil and water, biodiversity monitoring is also important to understand biological community in a habitat in order to check possible effects of changes due to proposed land development or management projects. Biodiversity assessment studies including flora and fauna can provide insights on the species presence, habitat use and suggest recommendations on effective use of an area (Niemelä 2000, Bajaru et al. 2020).

Raah Foundation approached Bombay Natural History Society (BNHS) for biodiversity assessment and biomass estimation of plantation of an ongoing ecological restoration project in Nashik, Maharashtra. The project aims to work towards restoration in the catchments of Godavari River in Nashik area through a series of plantation of native flora in upcoming years. The work includes biomass calculation of the plantation and inventorying key fauna in the study area. BNHS team undertook the monsoon season survey for multiple taxa such as plants, insects, herpetofauna, birds and mammals at different time periods during 30th August to 9th October 2023 at selected study sites.

Biomass Estimation of plantation

Biomass estimation pertains to the assessment of the quantity of living or organic matter within a particular geographical area, whether it be a forest, grassland, or wetland. Accurate determination of plant biomass is of paramount importance in ecological studies, particularly concerning the carbon cycle, ecosystem dynamics, and the implications of climate change on our natural environment (Santoro & Cartus, 2018). It is pivotal to recognize that plants play a pivotal role in sequestering atmospheric carbon dioxide through the process of photosynthesis, thus rendering them crucial contributors to mitigating the effects of climate change. Precise biomass estimates are invaluable in quantifying the carbon stored within diverse plant ecosystems, ranging from forests to grasslands, and provide invaluable insights for initiatives aimed at preserving and restoring carbon-sequestering ecosystems. Furthermore, biomass estimation assumes a pivotal role in monitoring changes in vegetation over time, identifying regions of significant conservation value, and informing decision-making processes related to land use and management (Heryati et al., 2011; Vorster et al., 2020).

Present report summarizes the multi-taxa observations taken during the survey at Anjneri hill along with estimations of biomass of the recent plantation.

1.1 Objective

- i. To record seasonal variation in species and prepare inventories of flora and fauna.
- ii. To estimate biomass of the plantation.

Fig. 1 Lush green site of Anjneri hill showing plantation pits and natural vegetation in monsoon

Fig. 2 Seasonal transformation of Anjneri hill during winter

2. Methodology

2.1 Study area

Anjneri hill, also known as Gadhwa dongar, is situated on south-west side around 24km away from Nashik city. The study site is a hillock present at an elevation of 810m above sea level. This site is closer to Trimbakeshwar from where the river Godavari originates and thereby it is closer to the Western Ghats. Although predominantly the habitat is of grassland type, there are many trees present at the base in the valley of the hill. Seasonal transformations of vegetation were seen during wet and dry seasons (Fig. 1 & 2).

2.2 Sampling

Seasonal variation and species inventory

Species inventory of flora and fauna was prepared by following the transects of 1km as shown in the map (Fig. 3). Opportunistic observations were also added to the final list. Seasonal variation was recorded by comparing species count across three seasons. Plant species which could not be identified on the field were identified using literature (Almeida 1996-2009). Birds and insects were mainly observed in daytime owing to their activity period in the morning 0730 to 1100hrs. Insects were surveyed considering all microhabitats i.e. on vegetation, and along water bodies. Nocturnal species of birds and insects were surveyed during evening 0530 to 0830hrs. Unidentified birds and insects were identified using relevant literature (Grimmett et al. 2011, Kehimkar 2016, Subramanian 2009).

Amphibians and reptiles, together called as herpetofauna, are mainly active during dark hours hence their surveys were carried out from 1900hrs to 0200hrs of the following day. Species were searched beneath rocks, barks, in culverts, streams, and rock cuttings. Extensive visual encounter surveys were also carried out along road nearby the study site. Few species were partially handled, identified, photographed, and subsequently released at the same location as where they were found. Identification of the species was based on visual observations, photographs, the use of field guides (Whitaker and Captain 2008, Daniel 2002) and literature on herpeto-fauna of British India (Smith 1931, Smith 1935, Smith 1943).

Presence of different mammals was also noted either by direct sighting or by indirect signs such as pugmarks, scraping marks and droppings using the relevant reference (Menon 2014).

Biomass estimation

To determine the biomass, the quadrat method was employed. The research effort involved the establishment of a total of 24 quadrats in the Anjneri site as shown in the map (Fig. 4). Specifically, two percent of the total number of planted saplings was sampled by laying quadrats of having size 7 pits by 3 pits plots. Additionally, the GPS coordinates of these quadrats were recorded to ensure precise location data. To distinguish the quadrats from the

surrounding saplings, ribbons were affixed to the four corner plants of each quadrat, demarcating their boundaries.

Calculations for both above-ground and below-ground biomass estimations of tree saplings were executed using allometric equations, as delineated in relevant academic sources (Chaturvedi & Raghubanshi, 2012; Yuen et al., 2016). These equations, informed by scientific research, serve as fundamental tools for accurately quantifying biomass in plant populations, and their utilization is imperative for the precision and rigor of the biomass estimation process in the study. We also noted essential parameters such as sapling height, bole diameter, and other pertinent characteristics, were measured directly in the field using measuring tape.

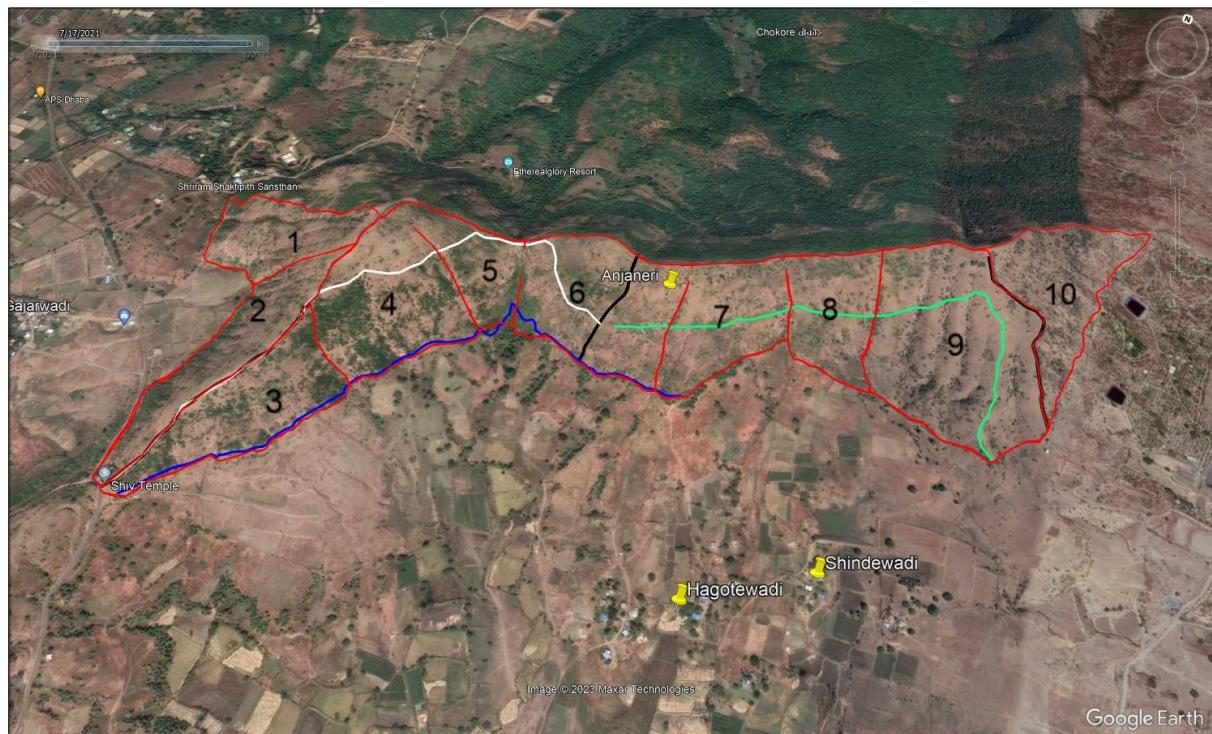

Fig. 3 Transects (blue, green & white) at Anjneri hill for biodiversity documentation

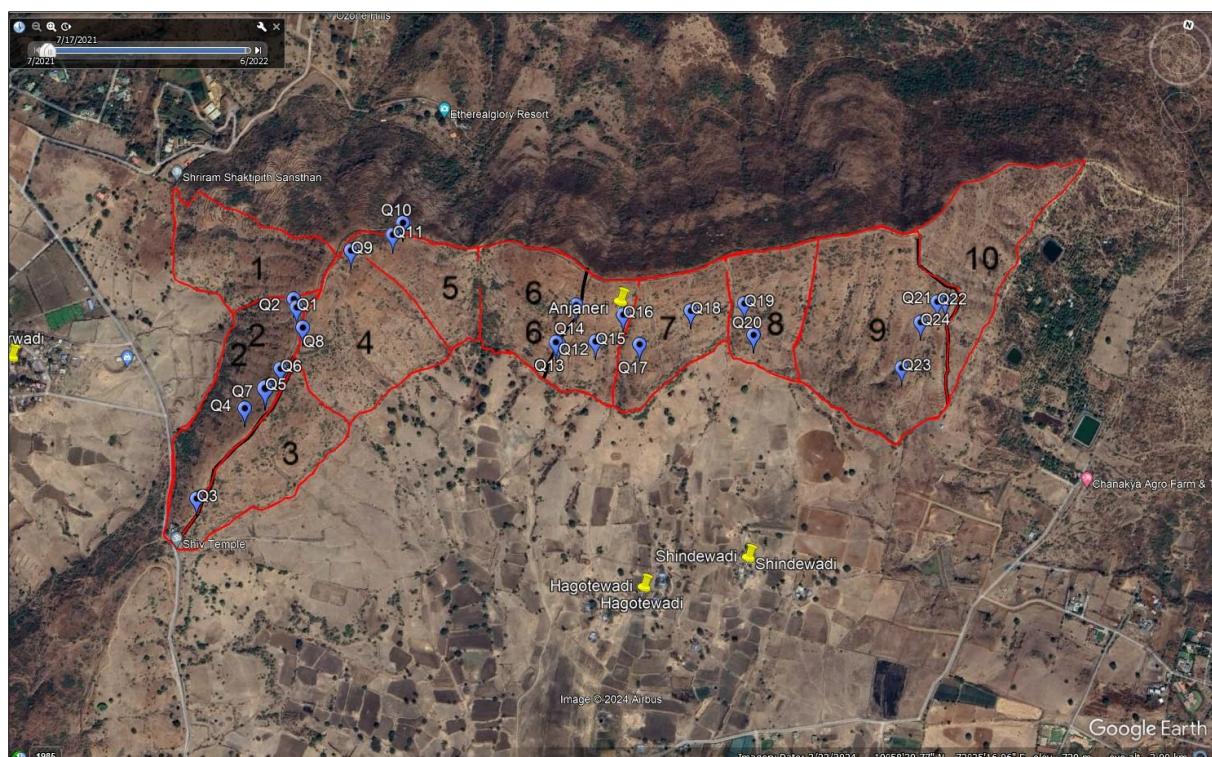

Fig. 4 Quadrats used for biomass assessments

3 Results

Taxa wise checklists of fauna and flora are given in following text under respective headings. Status provided by the global authority International Union for the Conservation of Nature (IUCN) in their Red List of Threatened Species, relevant remarks (native/introduced species) and protection provided by Indian law under the schedules of The Wild Life (Protection) Amendment Act, 2022 are also mentioned where applicable.

3.1 Flora

3.1.1 Species inventory

A total of 121 species belonging to 35 families were recorded across three seasons. Details of their habit, origin are given in the Annexure 1.

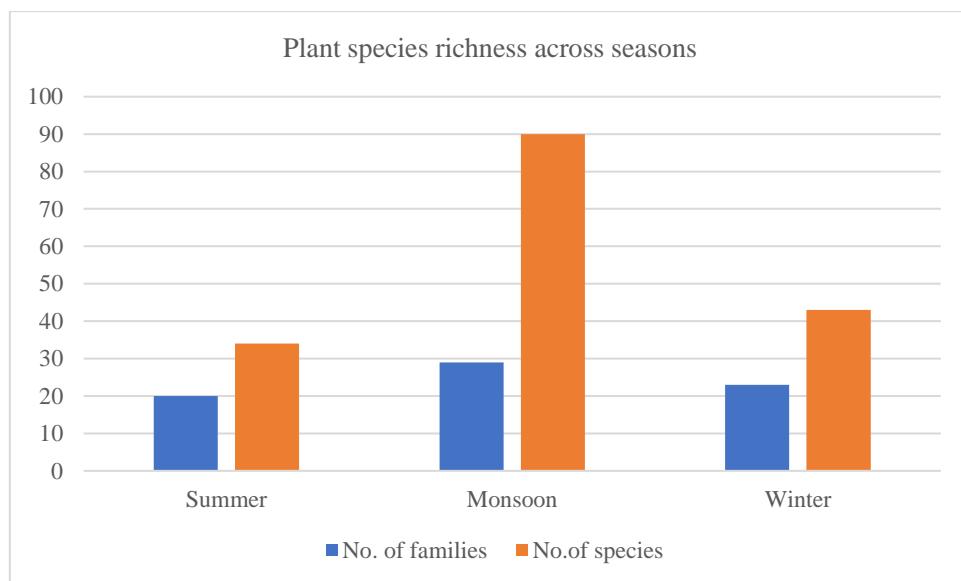

Fig. 5 Plant species richness across seasons at Anjneri

Majority of plant species at Anjneri are characteristics of grasslands and scrub forest. Out of total 121 species, almost 50% of the plants are herbs ($n=54$) followed by grasses ($n=27$). Some of these are annual that complete their breeding or flowering in monsoon in the suitable conditions. As mentioned earlier, trees were present at this site, generally at the base in the valleys or few on slopes. An individual of Banyan tree (*Ficus benghalensis*) was seen at the top near the boundary of zones nine and ten. *Ficus* spp. are usually known as flagship species as they support variety of other life forms like insects, parasites, birds etc.

As clearly seen in the figure no. 5, highest number of plants were recorded in monsoon ($n=90$) in which majority species are grasses, followed by winter ($n=43$). Out of the total species, almost 90% ($n=109$) plants were native. Grasses like *Heteropogon contortus*, *Sehima nervosum*, *Themda quadrivalvis*, *Borthicloa*, *Cymbopogon martini* and herbs like *Blainvellia*, *Indigofera*, *Trichodesma* sp., are typically found in open grasslands. Trees like *Terminalia crenulata*, *Butea* sp, *Bauhinia* sp, *Grewia tiliifolia* are scattered at slopes in the undulating valleys. Grasses and annual herbs started drying after monsoon (mid-October) onwards.

3.1.2 Biomass Estimation

The above-ground and below-ground biomass estimations of tree saplings were calculated for monsoon and winter season in all zones where plantation was done. The data collected in the winter season is given in the Annexure 2.

In monsoon (September 2023), data collected in total 16 quadrats regarding the above ground biomass of 207 saplings was 168.65 grams, with a corresponding below-ground biomass of 63.78 grams. The biomass estimation of the plantation in monsoon season corresponds to the total above-ground biomass 168.65 grams, and below-ground biomass of 63.78 grams.

In winter (January 2024), data collected in total 24 quadrats regarding the above and below ground biomass of total 426 sapling provides valuable insight into the biomass distribution within this valuable plantation. Estimating biomass in all zones of Anjaneri, from Zone 1 to Zone 9, is crucial for understanding the ecosystem's productivity and carbon storage capacity. In winter season, the total biomass across all zones was found to be 92.18 grams. This value represents the combined weight of all plant matter in the area, including above-ground 70.99 grams and below-ground biomass 21.18 grams. Such data is essential for ecosystem management, conservation efforts, and understanding the impacts of climate change on plant communities.

3.2 Insects

A total of 30 insect species belonging to 15 families and seven different orders were recorded across three seasons (Annexure 3).

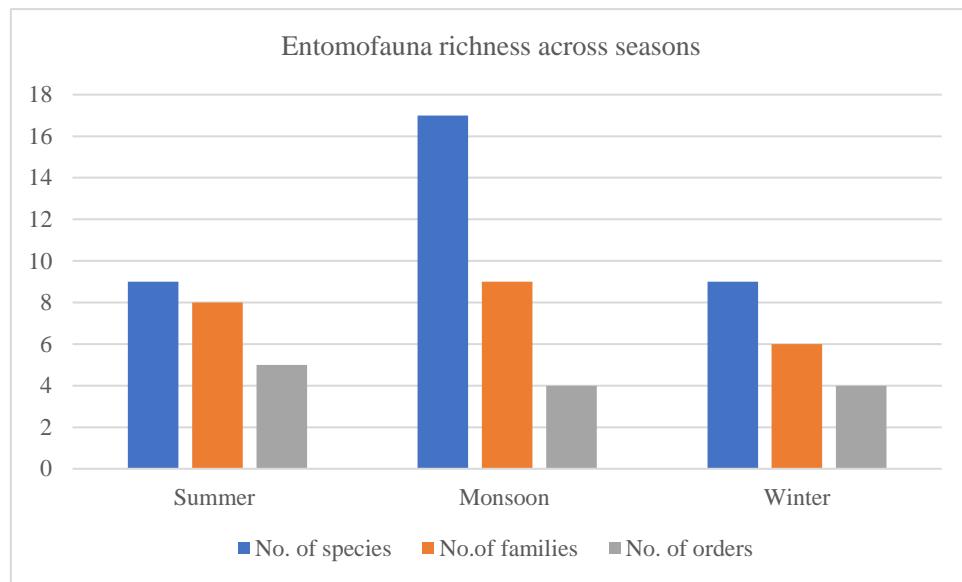

Fig. 6 Insect species richness across seasons at Anjneri

Highest number of species (n=17) were seen in monsoon season followed by equal number of species in summer and winter (n=9) but belonging to different orders but more number of families were seen in monsoon and summer (n=9 & 8, respectively). Certain insects like Cicadas were only seen in summer season. Highest number of recorded species belonged to order Lepidoptera (moths and butterflies). Although the habitat of Anjneri is open grassland, we did not detect any skippers among butterflies. Among the interesting observations, we recorded four caterpillars of different stages of a swallowtail butterfly *Papilio demoleus* (Lime Butterfly) on the sapling of *Limonia acidissima* Kavath in zone number 2 in monsoon season. It is a commonly found butterfly species mainly completing its life-cycle on plants of family Rutaceae. Another interesting observation was of Harvester ants (*Pheidole* sp.), also known as fortress ants due to their characteristic layered structure of nest generally built on slopes.

None of the species are included under any schedule of the Wild Life (Protection) Amendment Act, 2022. The species were identified to species level wherever possible barring some groups like ants, grasshoppers of which field identification is not possible in most of the cases. Out of identified species, none of the species are included under threatened categories as per IUCN Red List.

3.3 Herpetofauna

A total of five species of amphibians belonging to three families and nine reptiles belonging to five families were found across three seasons (Annexure 4).

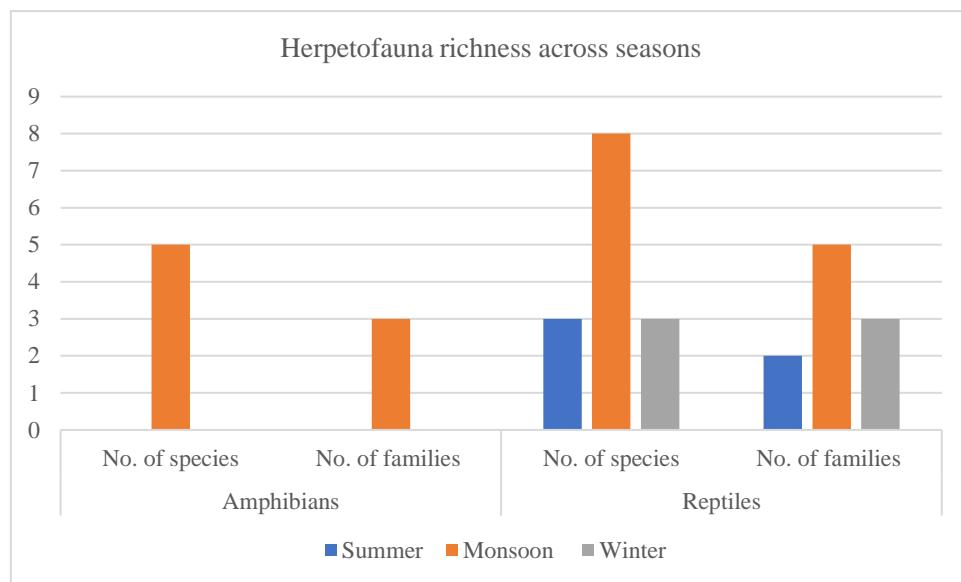

Fig. 7 Amphibian and reptile species richness across seasons at Anjneri

We did not record any amphibians in summer as well as winter season at Anjneri. Among reptiles, only Murray's House Gecko (*Hemidactylus cf. murrayi*) was found throughout all seasons. It is interesting to note that all the four species of snakes were spotted only in monsoon and one individual of Deccan Fan-throated Lizard (*Sarada deccanensis*) was seen in only summer season which is its breeding season. Overall, high species count and abundance was seen in the monsoon season. In case of reptiles, a higher number of species were seen in monsoon (n=8) than winter and summer (n=3 each).

As the life cycle of amphibians is dependent on freshwater, all five species were only found in monsoon in high numbers (n=10+). Among snakes, Checkered Keelback Snake, Rat Snake and Russell's Viper are protected under schedule I and Common Wolf Snake is protected under schedule II of The Wild Life (Protection) Amendment Act, 2022.

3.4 Avifauna

We recorded a total of 48 species of birds belonging to 28 families across three seasons in the study area (Annexure 5).

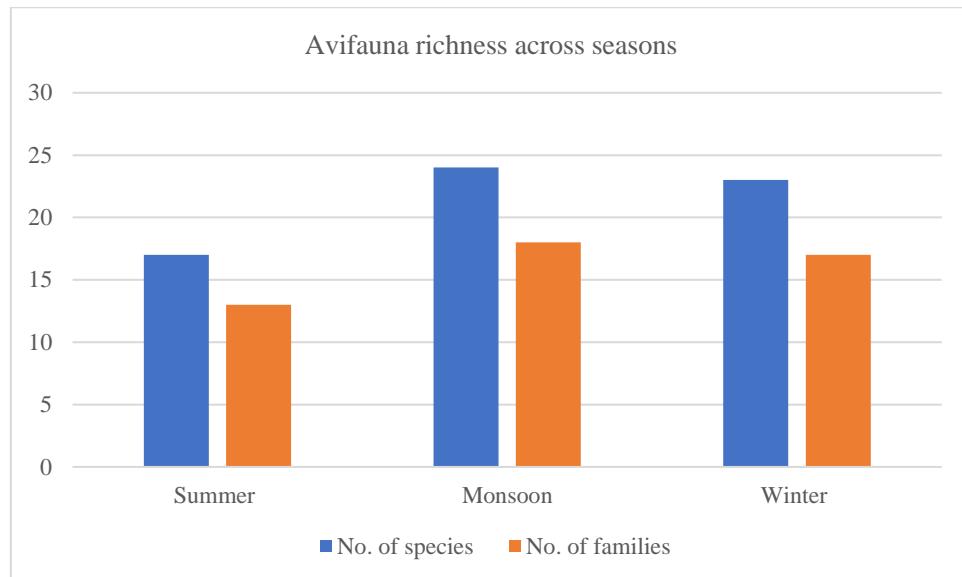

Fig. 8 Bird species richness across seasons at Anjneri

A higher number of species were observed in monsoon ($n=24$) and winter ($n=23$) season as compared to summer ($n=17$). Although the species richness is similar in monsoon and winter season, the composition varied in these two seasons. Out of the total 48 species, seven species are migratory and rest are resident. Out of these seven migratory species, migration of Jacobin Cuckoo is iconic meaning that although population in southern India is resident, the birds originating from eastern Africa arrive in Peninsular India at the start of monsoon hence the species is called as harbinger of monsoon or rain. The species was seen only during monsoon surveys. It is a brood parasitic bird which means it lays eggs in other bird's nests. Rest of the six species were mainly seen in the winter.

Among Bunting, we recorded a pair of Crested Bunting in monsoon whereas Grey-necked Bunting was found in winter. Both species are hill specialists often found in open rocky, grassy areas. They mainly feed on grass seeds, grains and occasionally on small insects. We also recorded Common Kestrel in which is a predatory bird, again inhabiting open grassy habitats.

Among other interesting observations, we recorded two individuals of Indian Vulture or Long-billed Vulture hovering above the study area in winter. The large rocky cliffs nearby the Anjneri reserve are perfect habitat for vultures and other raptors. The species is categorised as 'Critically Endangered (CR)' according to the Red List of International Union for Conservation of Nature (IUCN) due to severe population decline during 2000s.

4 Discussion

As observed throughout the year, our recordings indicate that the flora and fauna community of Anjneri hill is slightly different from other sites as it mainly closer to the Western Ghats and may be because the other side of the hill i.e. the one towards Chakore village is forested and not so open. Naturally occurring tree species are found at the base of this hill while the slopes were covered with grasses and shrubs e.g. *Euphorbia* spp. An increase in the biomass values was observed owing to increase in winter compared to monsoon as sampling efforts i.e number of quadrats sampled were more in the winter to accommodate the two percent sampling size. Also, some of the plots were seen burned in the fireline hence new adjacent quadrats were sampled. We suggest plantation of native plants over exotic varieties like Guava and Sitaphal. Priority must be given to trees naturally thriving in the area. Owing to the fact that the natural dominant elements are herbs and grasses (> 50%), care must be taken that plantations can alter the vegetation composition and thereby the ecosystem of the area. We discourage plantation of evergreen trees like Kaju (*Anacardium occidentale*) and Phanas (*Artocarpus heterophyllus*) as both naturally occur in high rainfall areas with high relative humidity, especially considering the hot dry conditions of the study site and irrigation challenges.

As a general trend, we saw higher number of species and abundance in the monsoon season due to favourable climatic conditions across all faunal taxa. Life stages of butterfly caterpillars were witnessed on some of the saplings like Kavath which is good indication of adaptation to vegetation by local fauna. An interesting observation among herpetofauna was of Roux's Forest Lizard which is mainly a forest-dwelling species. We had seen one individual of this species in summer at this site only and not at any other study sites. This might be due to there is a good vegetation cover on the other side of the hill that is why we are able to see an overlap between forest-dwelling species and the ones inhabiting open areas, as evident by the presence of Crested Bunting and Grey-necked Bunting, a typical hill species. Sighting of Indian Vulture or Long-billed Vulture in the area seems promising that its habitat is still intact and the area is used by the birds for foraging. It is a 'Critically Endangered (CR)' species according to the Red List of International Union for Conservation of Nature (IUCN).

Presence of mammals

Among mammals, we found droppings of Black-naped Hare (*Lepus nigricollis*) in the monsoon which is protected under schedule II of WPA, 2022. An exciting observation was recorded of the Striped Hyena (*Hyaena hyaena*) in the winter. It is the only hyena species found in India. We recorded an active den of an individual near zone 4 and 5 where a local saw an adult individual of hyena during survey that quickly vanished into its den. Locals are aware of the animal and fortunately there is no conflict between them. A decomposing remains of a domestic chicken was found near the den. Hyenas are usually scavengers feeding on the carcasses and remains of dead animals and hence regarded as ‘cleaners of the environment’. Presence of the animal indicates that it is surviving well in the habitat and it should be protected with high priority as the population of this species is declining due to habitat loss owing to land conversion. Hyenas mainly reside in rocky areas near grasslands and open scrublands. This species is categorised as ‘Near Threatened’ (NT) according to the Red List of International Union for Conservation of Nature (IUCN) with around 10,000 individuals surviving in the wild in India.

Also, we learnt from local people that Wild Boars (*Sus scrofa cristatus*) cause damage to the saplings by digging in the soil. There was notable digging activity near the base of bamboo saplings. The species *Sus scrofa* is protected under schedule II.

Striped Hyena

Hyaena hyaena

ABSTRACT
Striped Hyena *Hyaena hyaena* has most recently been assessed for The IUCN Red List of Threatened Species in 2014. *Hyaena hyaena* is listed as Near Threatened.
